Abstract. The study of biodiversity of anthropogenically disturbed areas is a prerequisite for assessing and predicting species abundance in regions. The present research aims at investigating the aquatic and coastal-aquatic flora and vegetation of the Sulem reservoir, built on the territory of the Visimsky nature reserve. Phytocoenotic material has been processed in accordance with the requirements of ecological-floristic classification of Braun-Blanquet. Flora analysis has been carried out in compliance with standard floristic methods. The study has revealed a variety of vegetation, which has been classified into 2 classes (Potamogetonetea and Phragmito-Magnocaricetea), 5 orders (Potamogetonetalia, Callitricho hamulatae-Ranunculetalia aquatilis, Phragmitetalia, Magnocaricetalia, Oenanthetalia aquaticae), 6 alliances (Nymphaeion albae, Potamogetonion, Ranunculion aquatilis, Phragmition communis, Magnocaricion elatae, Eleocharito Palustris-Sagittarion Sagittifoliae), 20 associations and 2 rankless communities. Communities of associations Elodeetum canadensis, Myriophylletum spicati and Callitrichetum hermaphroditicae are the most common in the territory under study. Large areas are covered with Sagittario sagittifoliae-Sparganietum emersi, Typhetum latifoliae and Typha intermedia. Communities of associations Potamo crispi-Ranunculetum trichophylli, Potamogetonetum graminei, Potamo natantis-Polygonetum natantis, Typhetum angustifoliae and Sparganietum erecti are less common. Flora of vascular plants include 66 species from 43 genera and 26 families. Cyperaceae (10 species), Poaceae (8 species), Potamogetonaceae (6 species), Ranunculaceae (4 species), and Typhaceae (4 species) are the leading families. Hydrophytes prevail among ecological groups. Eurasian boreal species prevail in the geographical structure of the flora. 2 species listed in the Red Book of the Sverdlovsk region include Nuphar lutea (L.) Smith и Nymphaea candida J. Presl.

1. Introduction

Study and conservation of biological diversity on regional and on global scale is very important today. This is due to the fact that biodiversity is one of the factors of optimal functioning of ecosystems and the biosphere as a whole [1, 2]. Quite often economic activity leads to changes in structure of biogeocenoses and disturbance of ecological balance. In this regard, the study of biodiversity in anthropogenically disturbed areas is a necessary condition for assessing and predicting species abundance in regions.

The territory of the Sverdlovsk region of the Russian Federation is home to the Visimsky reserve, which was founded in 1946 to preserve and study the typical and unique ecosystems of the South taiga middle Ural lowlands. In 2001, the reserve was granted the status of a biosphere reserve by UNESCO. Most area of the reserve is located in the upper reaches of the Sulem river, part of the vast Volga-

Kama basin. In the 1980s, 4 km² of the Visimsky reserve were transferred to the flooding zone. The reservoir created on the river Sulem was to solve the problem of drinking water supply of the city of Kirovgrad, located 30 km away from the reservoir. However, the water supply system has not been finished, and currently the reservoir is not used for supply of water to the city.

Creation of reservoirs significantly changes the landscape of river valleys, as well as the hydrological regime of the river within reservoirs. Reduction of the river flow speed often causes silting of artificial reservoirs. These factors lead to the emergence of a number of new landscape elements forming a zone of shallow waters, contributing to the formation and further development of aquatic and coastal-aquatic vegetation. Due to the relatively young age of the Sulem reservoir, its vegetation remains poorly studied.

The present research aims at investigating the aquatic and coastal-aquatic flora and vegetation of the Sulem reservoir, built on the territory of the Visimsky nature reserve.

2. Methods and materials

The area under study refers to the temperate continental climatic region. The average annual air temperature is 0.1 °C; the average duration of vegetation period (with average daily temperatures above 5 °C) is 152 days; the number of days with snow cover is 202; the average annual precipitation is 505 mm (with fluctuations from 350 to 700 mm) [3].

Field studies were conducted in July 2013. 34 geobotanical studies have been performed on test sites ranging in size from 2.5 to 100 m². Size of the sample area depends on the size and homogeneity of the community. Location of the geobotanical descriptions has been recorded using a GPS navigator (Fig. 1). Only vascular plants have been taken into account when performing geobotanical descriptions. Species names are given according to S. K. Cherepanov's report [4], as well as other modern taxonomic reports [5].

Figure 1. Map-scheme of the Sulem reservoir with localization of geobotanical descriptions

Phytocenotic material has been processed in accordance with the requirements of ecological and Braun-Blanquet's floristic classification [6, 7]. Geobotanical descriptions have been recorded in the TURBOVEG database [8] and processed using the JUICE program [9]. Works on aquatic and coastal-

doi:10.1088/1755-1315/579/1/012060

aquatic vegetation of Europe and Russia have been used to make syntaxonomic decisions [10–15]. Names of higher syntaxons are given according to "Vegetation of Europe..." [16].

Flora analysis has been carried out according to standard floristic methods. Ecological types are given according to V. G. Papchenkov [17]: hydrophytes, helophytes, hygrohelophytes, hygromeso- and mesophytes.

3. Results

Research results have shown that the vegetation of the Sulem reservoir is quite diverse and includes 2 classes, 5 orders, 6 alliances, 20 associations and 2 rankless communities. The system of syntaxons has the following form:

Class Potamogetonetea Klika in Klika et Novák 1941

Order Potamogetonetalia Koch 1926

The revealed associations and communities in the territory under study have a pronounced intrazonal character and have a simple structure, often monodominant (Tables I and II). Absence of communities of *Lemnetea* class is typical of the reservoir. Pleistophyte *Lemna minorL*. has been encountered only once in the community of association *Elodeetum canadensis*.

Cenoses of the association *Elodeetum canadensis* are the most common in the territory under study, while communities of the associations *Potamo pectinati-Myriophylletum spicati* and *Callitrichetum*

doi:10.1088/1755-1315/579/1/012060

hermaphroditicae are less common. Pondweed communities are mostly represented with Potamogeton perfoliatus. Potamo crispi-Ranunculetum trichophylli, Potamogetonetum graminei, Potamo natantis-Polygonetum natantis, Typhetum angustifoliae and Sparganietum erecti are rare communities of associations. Despite the relatively high syntaxonomic diversity, the described communities, especially those of the class Potamogetonetea, are characterized by poor species composition. Major part of the coastal-aquatic vegetation is concentrated along the left bank, which is flat and shallow. In this regard, the left-bank communities Sagittario sagittifoliae-Sparganietum emersi, Typhetum latifoliae and Typha intermedia are characterized by larger areas than the right-bank ones.

66 species of vascular plants from 43 genera and 26 families found in the aquatic environment or in drying shallow waters have been identified in the studied territory. They incude 2 species of Equisetales belonging to one family and one genus. Flowering plants are represented with 64 species belonging to 42 genera from 25 families. The monocotyledonous class is represented with 34 species belonging to 17 genera from 9 families. The dicotyledonous class is represented with 30 species belonging to 25 genera from 16 families.

ESCHIP 2020 IOP Publishing

IOP Conf. Series: Earth and Environmental Science 579 (2020) 012060

doi:10.1088/1755-1315/579/1/012060

5 families are characterized by the largest number of species taxa among vascular plants in the flora of the Sulem reservoir (Table III): *Cyperaceae* Juss. – 10 species, *Poaceae* Barnhart – 8 species, *Potamogetonaceae* Dumort. – 6 species, *Ranunculaceae* Juss. – 4 species and *Typhaceae* Juss. – 4 species. Other families are represented with only 1–3 species. 12 families are represented with only one species.

Table 3. The number of species in the 5 leading families of flora and their share in the number of vascular plants. %

Family names and other indicators	Number of species						
1. Cyperaceae	10 (15.2 %)						
2. Poaceae	8 (12.1 %)						
3. Potamogetonaceae	6 (9.1 %)						
4. Ranunculaceae	4 (6.1 %)						
5. Typhaceae	4 (6.1 %)						
Total number of species in 5 leading families	32 (48.6 %)						
Families with 2–3 species	9						
Families with 1 species	12						

Such distribution of the leading families in the studied flora, in general, is typical of many other groups of reservoirs described in the literature [12, 14].

At the genera level, *Potamogeton* and *Carex* are leaders in the number of species represented, with 6 species each. Since pondweed refers to species with high migratory activity, the undisputed leadership of the genus *Potamogeton* is observed in the aquatic flora of Russia and the world [18]. The genus *Typha* is represented with 4 species. Most of the genera (40 genera, or 93.0 %) are represented with only 1–3 species and contain 75.8 % of the list of species of the flora under study (50 species).

Analysis of ecological composition of the flora shows the predominance of hydrophytes in the hydrophilic flora of vascular plants of the Sulem reservoir (19 species, or 28.8 %). Hygrohelophytes, hygrophytes, hygromeso- and mesophytes account for 13 species each (or 19.7 %). Helophytes are represented with 8 species (12.1 %).

Geographical structure of the flora under consideration is characterized by the predominance of boreal (37 species, 56.1 % of the flora list) and plurizonal (24 species, 36.4 %) species in zonal distribution. Holarctic (24 species, 36.4 %) and Eurasian (22 species, 33.4 %) species dominate regionally. While taking into account both zonal and regional characteristics of the flora of vascular plants of the Sulem reservoir, it is possible to note a significant predominance of Eurasian boreal species (16 species, or 24.2 % of the total flora list) and, to a slightly lesser extent, Holarctic plurizonal (12 species, or 18.2 %) and Holarctic boreal species (11 species, or 16.7 %). These 3 groups contain more than half of the list of considered flora (59.1 %).

Conservative nature of reservoirs' aquatic environment creates favourable conditions for widespread plurizonal species. Moreover, the location of the Sulem reservoir determines a significant shift in the geographical spectrum towards Holarctic and Eurasian, as well as boreal species.

The studied flora is also characterized by extremely low presence of adventitious plant species in comparison with similar flora located in the more populated regions of the Urals [19]. Among adventitious plant species, only *Elodea canadensis* probably introduced by waterfowl has been recorded. This factor indicates a weak anthropogenic disturbance of the territory of the Sulem reservoir.

2 species listed in the Red Book of the Sverdlovsk region have been found in the studied water area [20]: *Nuphar lutea* (L.) Smith и *Nymphaea candida* J. Presl.

4. Conclusion

Thus, the vegetation of the Sulem reservoir includes 2 classes, 5 orders, 6 alliances, 20 associations and 2 rankless communities. The revealed associations and communities have a pronounced intrazonal character and a simple structure, often monodominant. Communities of associations *Elodeetum canadensis*, *Myriophylletum spicati* and *Callitrichetum hermaphroditicae* are the most

doi:10.1088/1755-1315/579/1/012060

common in the territory under study. Rare associations include *Potamo crispi-Ranunculetum trichophylli*, *Potamogetonetum graminei*, *Potamo natantis–Polygonetum natantis*, *Typhetum angustifoliae* and *Sparganietum erecti*.

The flora of vascular plants includes 66 species from 43 genera and 26 families. The leading families are Cyperaceae (10 species), Poaceae (8 species), Potamogetonaceae (6 species), Ranunculaceae (4 species), Typhaceae (4 species). Hydrophytes dominate among environmental groups, and Eurasian boreal species dominate in the geographical structure. The studied flora is also characterized by extremely low presence of adventitious plant species in comparison with similar flora located in more populated regions of the Urals [19].

Acknowledgment

The research has been funded by the administration of the Visimsky State natural biosphere reserve.
